“The First Public, Web-Accessible Database  
with Information on Molecular Recognition”

MKG, Bourne, Westbrook

Experimental conditions, other associated data

Protein-ligand, protein-protein, nucleic acids, host-guest

# Binding Databases: Important Components of the Bioinformatics Infrastructure

- Accommodate data sets too large to be published
- Accommodate raw data, making reanalysis possible
- Facilitate lead compound discovery
- Validate and improve computer-aided drug design software
- Flag risk of side-effects, based on chemical similarity
- Elucidate mechanisms of bioactive compounds  
Identify biomolecules bound by chemical similars

# “The database is now up and running...”

2000-2001

“The next key task is to gather data. This proves to be somewhat challenging...”

## Editorial

### The bioinformatics of molecular recognition

The establishment of the major gene and protein databases, and the imperative to interpret and use the data they contain, have created the field of bioinformatics. However, while the major biomolecular databases focus almost exclusively on single molecules, it is fundamentally the *interactions* among biomolecules that endow them with function—a fact that needs no emphasis in the pages of *Journal of Molecular Recognition*.

It is thus significant that, in the last few years, databases have finally been established to archive and present data on molecular binding interactions. Two of these databases—the Database of Interacting Proteins (DIP; <http://dip.doe-mbi.ucla.edu/>) and the Biomolecular Interaction Network Database (BIND; <http://www.bind.ca/>)—focus on listing binding interactions among naturally occurring molecules, as determined by 2-hybrid studies, for example. However, readers may be more interested in the *quantitative* binding data in the Thermodynamic Database for Protein-Nucleic Acid Interactions (ProNIT; <http://www.rtc.riken.go.jp/jouhou/pronit/pronit.html>) and this author's Binding Database (BindingDB; <http://www.bindingdb.org>). Both data collections are young but growing. ProNIT, which is limited to protein-nucleic acid binding, currently lists *ca*2000 binding interactions involving 92 different proteins. BindingDB, which collects data for all kinds of molecules and complexes, including synthetic compounds and mutant biopolymers, currently lists *ca*250 binding interactions involving about 100 different molecules.

What is a molecular recognition database good for? A number of uses are readily envisioned. For example, after identifying a protein of interest in GenBank or SwissProt, it is natural to ask what other molecules it binds. In cases where one wishes to understand a biological system better, one will be interested in interactions with naturally occurring proteins or nucleic acids. For drug design, small organic ('drug-like') compounds may be more important. For example, an extensive binding database could facilitate the discovery of lead compounds by allowing one to quickly identify small molecules that bind homologs of a targeted protein. Conversely, if the database shows that a drug candidate binds many different proteins, this might indicate a high risk of side-effects. And for theoreticians, ready access to a range of binding data would facilitate the development of quantitative models of binding for use in molecular modeling and drug design.

In order to support all of these activities, BindingDB collects binding data on both naturally occurring and synthetic compounds. Affinities of course depend upon experimental conditions, so BindingDB stores not only the measured affinities themselves, but also pH, temperature and buffer composition, along with materials and methods that are important for reproducing and assessing the data. Currently, BindingDB contains measurements by isothermal titration calorimetry only, but measurements by enzyme

inhibition assays should be available soon—possibly by the time this piece is printed—and other techniques will be accommodated in the future. Measurement techniques are added one by one because the database must be expanded to accommodate each technique's special features. (For example, enzyme-inhibition methods require that the substrate be specified.)

The database is now up and running, providing a range of search methods, including searches by keyword, author, molecule name, protein sequence homology and chemical similarity and substructure. The next key task is to gather data. This proves to be somewhat challenging—certainly more so than collecting DNA sequences, which are poured out in electronic format by automated instruments. In contrast, most molecular recognition data are locked away in journal articles where they can be read by humans but not readily parsed into database fields by a computer. The problem is being addressed in two ways. First, authors are invited to enter their binding data via the on-line forms provided at the database's web-site. The only restriction is that the methods used to generate the data be published in a refereed journal. Note that, although the forms request a detailed description of the measurements, the author who is pressed for time need enter only the relatively few mandatory items, which are marked as such on the data entry forms. Also, data can be corrected at any time by the author, even after they are in the database and available on the web. Depositors should feel free to ask BindingDB staff for help with the deposition process. Second, software tools are being developed that will speed the recovery of binding data from articles that are already published, but it will take some time before these methods are operational.

Future plans for BindingDB include the creation of more sophisticated search and analysis tools at the web-site and integration with other biomolecular databases. For example, it should be possible to link directly from GenBank sequences to BindingDB in order to discover compounds that bind a protein of interest; and correlations between structure and energetics should be supported via links with the Protein Data Bank (<http://www.pdb.org>) and with the protein-ligand database Relibase (<http://relibase.ebi.ac.uk>). Given the progress already made in establishing BindingDB and other molecular interaction databases and the importance of molecular recognition in biology, pharmaceuticals and chemistry, binding data appear on track to become an important component of the bioinformatics infrastructure.

### Info

BindingDB is a public, web-accessible database of measured binding affinities, focusing chiefly on the interactions of proteins considered to be candidate drug-targets with ligands that are small, drug-like molecules. BindingDB supports medicinal chemistry and drug discovery via literature awareness and development of structure-activity relations (SAR and QSAR); validation of computational chemistry and molecular modeling approaches such as docking, scoring and free energy methods; chemical biology and chemical genomics; and basic studies of the physical chemistry of molecular recognition. BindingDB also includes a small collection of host-guest binding data of interest to chemists studying supramolecular systems.

The data collection derives from a variety of measurement techniques, including enzyme inhibition and kinetics, isothermal titration calorimetry, NMR, and radioligand and competition assays. BindingDB includes data extracted from the literature by the BindingDB project, selected PubChem confirmatory BioAssays, and ChEMBL entries for which a well defined protein target ("TARGET\_TYPE='PROTEIN'") is provided. Data extracted by BindingDB typically includes more details regarding experimental conditions, etc. BindingDB currently contains about 620,000 binding data for 5,500 proteins and over 270,000 drug-like molecules. Data from ChEMBL is provided under a [Creative Commons Attribution-Share Alike 3.0 Unported License](#).

# Cytoscape Pathways and BindingDB

## Proteins to Small Molecules and Affinities

The screenshot displays the Cytoscape Desktop interface (Session: FAS (CD95) signaling pathway.cys). The main window shows a complex network of nodes and edges. A context menu is open over a node labeled **48-800482699-pid\_m\_202242**. The menu options include:

- Visual Mapping Bypass
- Nested Network
- Use Web Services
- Hide Node
- LinkOut

The **LinkOut** option is selected, opening a sub-menu with the following options:

- Database
- Reactome
- Model Organism DB
- Array Express
- Ensembl Gene View
- KEGG
- Entrez
- Interaction Databases
- iHOP
- Other Biological DB
- BindingDB
- EBI Tools
- UniProt
- Ontology
- Search Engines

The **BindingDB** option is highlighted, opening a sub-menu with the following options:

- BindingDB (canonical name)
- BindingDB (UniProt)

The **Results Panel** on the right shows the details for the selected node:

**MEKK1 (cleaved)\_0-0**  
Protein  
Links:  
- [UNIPROT: Q13233](#)

The **Data Panel** at the bottom shows a table with the following columns:

ID	biopax.xref.PUB...	biopax.entity.DATA-SOURCE	biopax.entity.N...	biopax.xref_ids	biopax.protein.ORG...	biopax.entity_t...	biopax.dataSou
48-800482699-pid_m_202242		[Pathway Interaction Database]	MEKK1 (cleaved)_0-0	[UniProt Q13233]	Homo sapiens	Protein	[Pathway Interaction Databa

The **Visual Mapping Browser** on the left shows the default visual style for the network, including node and edge properties.

Start xplorer<sup>2</sup> - George's File... Inbox - Mailbox - Nicol... Maryland and Colorad... My Yahoo! - Google C... Cytoscape Desktop ... 10:33 AM

The screenshot displays the Cytoscape Desktop application window. The title bar reads 'Cytoscape Desktop (Session: thymidine\_test.cys)'. Below the menu bar (File, Edit, View, Select, Layout, Plugins, Help), there is a toolbar with icons for file operations and a search field. The 'Control Panel' on the left contains tabs for 'Network', 'VizMapper™', 'Editor', and 'Filters'. A table within the 'Network' tab shows the following data:

Network	Nodes	Edges
PSICQUIC Query Results: Fr...	2(1)	1(0)
BindingDB	88(1)	136(0)

The main visualization area shows two distinct network clusters. The top cluster is a dense, circular network of nodes (represented as small blue squares) connected by numerous edges. The bottom cluster is a smaller, less dense network. The 'Data Panel' at the bottom left shows a table with a single header 'ID' and one entry 'BindingDB\_...'. Below the data panel are three tabs: 'Node Attribute Browser', 'Edge Attribute Browser', and 'Network Attribute Browser'. The status bar at the bottom provides instructions: 'Welcome to Cytoscape 2.7.0', 'Right-click + drag to ZOOM', and 'Middle-click + drag to PAN'. The Windows taskbar at the very bottom shows the Start button and several open applications, including 'xplorer<sup>2</sup>', 'Inbox - Mailbox', 'Maryland and Colorad...', 'My Yahoo! - Google C...', and 'Cytoscape Desktop ...'. The system clock indicates the time is 10:33 AM.
